transfer can be enhanced This would lead to greater production of electricity energy or other products Electrochemically active microorganisms EAMs are a group of microorganisms which are able to release electrons from inside their cells to an electrode or accept electrons from an electron donor The way in which EAMs do this is called extracellular electron transfer EET So far two EET mechanisms have been identified direct electron transfer from microorganisms physically attached to an electrode and indirect electron transfer from microorganisms that are not physically attached to an electrode 1 Direct electron transfer between microorganisms and electrode can occur in two ways a when there is physical contact between outer membrane structures of the microbial cell and the surface of the electrode b when electrons are transferred between the microorganism and the electrode through tiny projections called pili or nanowires that extend from the outer membrane of the microorganism and attach themselves to the electrode 2 Indirect transfer of electrons from the microorganisms to an electrode occurs via long range electron shuttle compounds that may be naturally present in wastewater for example or may be produced by the microorganisms themselves The electrochemically active biofilm which degrades contaminants and produces electricity in MESs consists of diverse community of EAMs and other microorganisms However up to date only a few EAMs have been identified and most studies on EET have focused on the two model species of *Shewanella oneidensis* and *Geobacter sulfurreducens* **Scientific American** ,1917
